

# PHY 481/581 - FINAL EXAM REVIEW FALL 2018

---

## 1 Specific Heat in Solids in Ch. 2

- Einstein solid – the discrete allowed energy values lead to a temperature-dependent heat capacity
- Debye solid – Debye's model incorporated the coupling between harmonic oscillators further modifying the heat capacity at low- $T$

## 2 Free electrons in metals Ch. 3 & Ch. 4

- Classical theory for electrons in electric and magnetic fields – Drude theory – electrons modeled as a charged classical “gas.”
- Fermi-Dirac statistics – the Pauli exclusion principle places restrictions upon energy values for the electrons in a gas

## 3 Phonons Ch. 9 & Ch. 10

- Monatomic 1D solid vibrations – as wavelength of sound wave approaches the inter-atomic spacing, the dispersion relation deviates from linear
- Diatomic 1D solid vibrations – for two atoms of different mass, the dispersion relation splits into two branches: acoustic and optical

## 4 Crystal geometry Ch. 12, Ch. 13, & Ch. 14

- Crystal structure – unit cells, Bravais lattices, and the rest
- Waves in crystals – reciprocal lattice, families of planes
- The Bragg and Laue conditions – waves typically pass through a periodic potential unimpeded unless these equivalent conditions are met, at which time reflection occurs
- X-ray diffraction – structure factor, selection rules

## 5 Electronic band theory Ch. 15, Ch. 16, Ch. 17, & Ch. 18

- Electrons in a periodic potential – nearly free electron model, Bloch's theorem
- Electrical conductivity in solids – metals, semiconductors and insulators, band-gaps, Fermi surface
- Semiconductor physics – doping, heterojunctions
